

## REAL GAINS

# Faster is not more productive, it is just faster.

How to measure a productivity gain that genuinely exists.

## AND THE CONSEQUENCE

Without quality, volume and cost in the same math, speed hides the rework.

## THE CASCADE

# The easiest measure is the one that fools you most.

## WHAT YOU SEE

**The tool arrives and the team delivers faster.**

## THE MECHANISM

**Nobody measures errors, rework or total cost.**

## THE CONSEQUENCE

**Two months later the bill shows up in another team's queue.**

| Speed with no quality is not a gain. It is debt on a short fuse.

## THE FORK

# What do you have recorded from before?

## YOUR BEFORE

01

**Nothing at all?**

then any number afterward is an opinion

02

**Only the time?**

you are measuring half of productivity

03

**Time, errors, volume and cost?**

then you can talk about a gain

Whoever did not record the before cannot claim the after.

## THE METHOD

# The Four Measures.

01 **TIME**

how long the cycle took, from request to delivery

02 **QUALITY**

how many errors and reworks came back per hundred deliveries

03 **VOLUME**

how much went out per person per week, in the same unit

04 **COST**

how much each delivered unit cost, including the tool

All four together or none. One on its own always finds a way to improve.

WHAT TO ASK, IN ORDER

# Four questions, one per measure.

01 • TIME

**How long did it take from request to delivery?**

the whole cycle, not the automated stage

02 • QUALITY

**How many came back to be redone?**

per hundred, and for what reason

03 • VOLUME

**How much went out per person per week?**

in the same unit as before

04 • COST

**How much does each unit cost now?**

with the licence inside the math

TWO MODELS

# The impression of a gain and a measured gain.

THE COMMON MODEL

## Impression

Measures time only

Compares against the memory of before

Ignores the cost of the tool

The gain vanishes when someone audits

THE DESIGNED MODEL

## Measured gain

Measures time, quality, volume and cost

Compares against a recorded before

Puts the licence inside the math

The gain survives the audit

## MISTAKE AND CONSEQUENCE

# Three measurement traps.

## 01 Measuring the stage instead of the cycle.

- the stage speeds up and the next queue swallows the gain.

## 02 Comparing against memory.

- memory always favors the decision already made.

## 03 Leaving the tool cost out.

- a gain that ignores the price is not a gain, it is a transfer.

The first is the most common and the most expensive, because it looks like rigor.

## THE CHAIN

# The before test.

01 Ask whoever defends the gain for the before number.

02 See whether it exists on record, with a date.

03 If it does not, the conversation is over, and the gain is a hypothesis.

WHERE LEADERSHIP STEPS IN

Recording the before takes a week. Arguing without it takes the whole year.

RUN IT THIS WAY NEXT TIME

# Three moves before the next pilot.

|                                                                                                                               |                                                                                                                                                                        |                                                                                                                                         |
|-------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <div>▣</div> <div>STEP 01</div> <div><b>Record the four measures for two weeks.</b></div> <div>before any tool comes in</div> | <div>▣</div> <div>STEP 02</div> <div><b>Pick the unit and never change it.</b></div> <div>per delivery, per ticket, per proposal, it does not matter, but fix it</div> | <div>■</div> <div>STEP 03</div> <div><b>Recalculate everything ninety days later.</b></div> <div>with the licence inside the cost</div> |
|-------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|

Two weeks of recording beat six months of arguing about perception.

THE MODEL THAT STICKS

# The Four Measures, a loop and not a list.

Whoever did not record the before cannot claim the after.

SAVE THIS FOR LATER

before you announce the next productivity gain.
