

THE MANAGER'S ROUTINE

Automating an unstable process is multiplying the error with punctuality.

What a manager should automate first.

AND THE CONSEQUENCE

The question is not what can be automated, it is what is already right.

THE CASCADE

Automation starts with the most visible thing.

WHAT YOU SEE

You pick the most annoying process to automate.

THE MECHANISM

It is annoying precisely because it was never stabilized.

THE CONSEQUENCE

Now the error happens on its own, on schedule, every week.

Automation is an amplifier. It amplifies what works and amplifies crooked design.

THE FORK

Is this task ready to leave your hands?

READY TO LEAVE

01

Does it come out differently each time?

stabilize first, automate afterward

02

Does any step need your judgment?

that step stays, the rest can go

03

Does it come out the same every time,
without you thinking?

then it is ready

Whatever still needs judgment is not a candidate for automation. It is a candidate for a written criterion.

THE METHOD

The Sieve, four holes.

01 **REPEATS**

it happens every week, in the same shape

02 **STABLE**

the process is already right, you will not automate the error

03 **NO JUDGMENT**

no step depends on a decision of yours

04 **HURTS TODAY**

it eats time you need for designing

Passed all four, automate it. Failed one, fix that one first.

WHAT TO ASK, IN ORDER

Four questions per task in your week.

01 • REPEATS

Does this happen every week in the same way?

if it varies, it is not routine yet

02 • STABLE

Does the process already work when done by hand?

if it does not, automating makes it worse

03 • NO
JUDGMENT

Does any step need you to decide?

separate that step before automating the rest

04 • HURTS
TODAY

How much time does this cost you per week?

in hours, not in feelings

TWO MODELS

Two ways to choose what to automate.

THE COMMON MODEL

By annoyance

Starts with what irritates most

Automates an unstable process

Measures by the feeling of relief

The error starts happening on its own

THE DESIGNED MODEL

By the sieve

Starts with what is already stable

Stabilizes before automating

Measures by the hours handed back

The recovered time becomes a design block

MISTAKE AND CONSEQUENCE

Three automations that come back as problems.

01 Automating before stabilizing.

- you swap an occasional error for a punctual, recurring one.

02 Automating the step that needs judgment.

- the decision becomes a rigid rule and the exception becomes a crisis.

03 Not deciding what to do with the recovered time.

- it gets taken by urgency in less than two weeks.

The third is the most common. With no destination, the saved time vanishes without a trace.

THE CHAIN

The Wednesday test.

01

Look at last Wednesday, hour by hour.

02

Mark what you would do again exactly the same way.

03

That list is your automation queue, ordered by time consumed.

WHERE LEADERSHIP STEPS IN

No external diagnosis needed. One honest Wednesday hands you the whole list.

RUN IT THIS WAY NEXT TIME

Three moves this week.

▣ STEP 01 Log the hours of one Wednesday. improving nothing, only recording	▣ STEP 02 Run each item through the four holes. whatever fails on stable becomes a stabilization project	■ STEP 03 Decide the destination of the time before you free it. with no destination, urgency takes it
--	---	---

Start with the dullest task that passes all four holes. It leaves your life in one day.

THE MODEL THAT STICKS

The Sieve, in the order that matters.

Automation does not fix design. It repeats it with precision.

SAVE THIS FOR LATER
next Wednesday, hour by hour.
